

The Spread of Anti-trafficking Policies – Evidence from a New Index

Seo-Young Cho^a

Eric Neumayer^c

August 2011

Abstract: The *United Nations Convention against Transnational Organized Crime* and its *Protocol to Prevent, Suppress and Punish Trafficking in Persons, especially Women and Children* require countries to enact policies aimed at the prevention of human trafficking, the prosecution of traffickers and the protection of trafficking victims. We analyze the spread of this triple set of policies across countries. Arguing that countries are unlikely to make independent choices, we identify pressure, externalities and learning or emulation as plausible diffusion mechanisms for spatial dependence in anti-trafficking policies. We develop a new index measuring governments' overall anti-trafficking policies for 177 countries over the 2000-2009 period. We also assess a country's level of compliance in the three main constituent dimensions of anti-trafficking policies – prosecution, protection and prevention. Employing a spatial autoregressive model, we find that, with the exception of victim protection measures, anti-trafficking policies diffuse across contiguous countries and main trading partners due to externality effects. We find evidence for learning or emulation effects in all policy domains, with countries looking toward peers with similar political views or cultural values. Surprisingly, major destination countries do not seem to exert pressure on relevant main countries of origin or transit to ratchet up their policies.

Keywords: human trafficking, human rights, spatial dependence of policies

JEL codes: O15, F22, P41

1. Introduction

In the last few decades, human trafficking has become a growing phenomenon worldwide. The illicit trade in human beings across borders violates the human rights of victims, threatens national security and deteriorates the health of the affected economies and societies by increasing the size of the shadow economy and organized criminal activities (Belser 2005). Although the exact magnitudes and dimensions of the problem are unknown, available statistics suggest that human trafficking is one of the most serious transnational crimes in the 21st century. According to the U.S. Department of State (2010), there are more than 12 million victims of human trafficking worldwide. Interpol (2009) estimates that human trafficking is a multi-billion-dollar business, amounting to the third largest transnational crime following drug and arms trafficking.

Human trafficking can be seen as one of the dark sides of globalization. As advancements in technology and transportation connect countries more closely regardless of geographical distances, illicit flows of human beings have also become a global phenomenon. Anecdotal evidence suggests that traffickers recruit victims worldwide and transfer them from one country to another, often across continents (U.S. Department of State 2010). For instance, according to the UNODC (2006), trafficking victims found in the United States came from 66 countries in different regions (China, Mexico and Nigeria for example). Germany, another major destination, receives trafficking victims from at least 51 countries, including many from outside Europe (Afghanistan, Colombia, the Dominican Republic, etc.).

Given the growing significance of international human trafficking, it is no surprise that the international community has adopted several measures in the past ten years, including the *United Nations Convention against Transnational Organized Crime* and its *Protocol to Prevent, Suppress and Punish Trafficking in Persons, especially Women and Children* (2000, hereinafter the “Convention” or “Protocol”), which require countries to adopt policies against human trafficking in the form of policies aimed at the prevention of the crime, at the prosecution of offenders and the protection of victims. In this article, we analyze how these policies have spread across countries, testing for spatial dependence in policy choices.

Social scientists have started to turn their attention towards policies enacted to combat human trafficking (Akee et al. 2010; Auriol and Mesnard 2010; Avdeyeva 2010; Bartilow 2010; Cho and Vadlamannati 2011; Di Tommaso et al. 2009; Friebe and Guriev 2006; Mahmouda and Trebesch 2009; Simmons and Lloyd 2010). One of the problems scholars face is the lack of reliable data on countries’ anti-trafficking policies which can be compared over time and between countries. The U.S. Department of State reports a ranking of countries with

respect to their actions in fighting human trafficking. They use a scale of 1-3,¹ which is based on the level of compliance with the United States 2000 Victims of Trafficking and Violence Protection Act (TVPA). However, the tier ranking has several drawbacks, which limit its reliability and relevance.² In particular, while the tier ranking provides an aggregate score of compliance with anti-trafficking policies, it fails to recognize the different levels of compliance in the three main policy dimensions – prosecution, protection and prevention. Separating the three dimensions is important. Theory and evidence indicate that better protection policy may encourage potential victims to risk illegal migration, which could lead them to fall prey to traffickers. Human trafficking inflows might therefore increase as a consequence, contradicting the objectives of prosecution and prevention policies (Akee et al. 2010). Countries can thus have the same overall ranking on the index, but for very different reasons.³

We make two important contributions to the growing literature on human trafficking. First, we develop novel and original indices of anti-trafficking policies around the world, providing better, more detailed and disaggregated measures of the three prime policy dimensions enacted by countries. Specifically, we use raw data from two reports on human trafficking – the Annual Reports of Trafficking in Persons (United States State Department, 2001-2010) and the Reports on Trafficking in Persons: Global Patterns (United Nations Office on Drugs and Crime, 2006 and 2009) – to construct separate indices on the three policy dimensions (prosecution, protection and prevention), as well as one overall aggregate anti-trafficking policy index for up to 177 countries over the 2000-2009 period. The index provides a score from 1 to 5 for the level of compliance, with each dimension of anti-trafficking policies for each country and year. Second, we argue that policy choices across countries are very unlikely to be independent from each other. Major destination countries will wish to push for policy changes in relevant transit and origin countries. More generally, international human trafficking creates significant cross-country externalities and countries

¹ The tier-ranking consists of tier 1, 2, 2-watchlist and 3. “Tier 2” and “tier 2-watchlist” reflect the same level of compliance (with ‘watchlist’ providing information about a country’s development relative to the previous year).

² The decision rule of the tier-ranking is not transparent to the public. It is not clear how the three levels of the ranking – full compliance, significant efforts and no significant efforts – are assessed and determined, making the ranking vulnerable to subjectivity (GAO 2006). It has been argued the tier-ranking is largely a tool of the U.S. government to influence other country’s policies through ‘naming’ and ‘shaming’ (Simmons and Lloyd 2010). It is determined based on evaluation of compliance with the United States’ domestic anti-trafficking law – the Victims of Trafficking and Violence Protection Act (TVPA 2000) – rather than international law. Its relevance for evaluating international standards is therefore limited.

³ A number of countries in full compliance with the tier-ranking fail to ensure the basic legal rights of victims, punishing and deporting them, while demonstrating sound policy interventions in the other dimensions (prosecution and prevention). For instance, in the tier 1 group, victims in France and the United Kingdom were reportedly imprisoned and deported due to their actions related to the situations in which they were trafficked in 2008 and 2009 (U.S. Department of State, 2009 and 2010).

will also want to learn from or emulate the policies enacted by other countries. Because of these cross-country spillover effects, we argue that countries spatially depend on each other in their respective policy choices. We empirically investigate this hypothesis with a spatial autoregressive estimation model.

To foreshadow our results, we find evidence for spatial dependence in anti-trafficking policies. In particular, policies diffuse via externality effects across contiguous countries and main trading partners – with the exception of protection policies, for which one would not expect any externality effect. Policies also diffuse via learning or emulation effects as countries look for cues (or information) from other countries sharing political and cultural similarities. However, we do not find any significant effect of pressure from the United States via aid. Nor do we find evidence that major destination countries pressurize relevant major transit and origin countries to enact stricter anti-trafficking policies.

We proceed as follows. In section 2, we develop theoretical arguments as to why anti-trafficking policies are not independently chosen by countries. In section 3, we introduce our indices on anti-trafficking policies. The method of estimation and data are described in section 4, while we discuss our results in section 5. Section 6 tests for the robustness of our results. The final section concludes the paper.

2. Spatial Dependence in Anti-trafficking Policies

Spatial dependence in policy choices has become a key concept in the recent literature analyzing policy diffusion across countries (Neumayer and Plümer 2010; Gassebner et al. 2011; Gauri 2011; de Soysa and Vadlamannati 2010; Greenhill et al. 2009; Eichengreen and Leblang 2008; Pitlik 2007; Blonigen et al. 2007). Spatial dependence exists whenever the marginal utility of one unit of observation (here: a country) is affected by the decision-making of other units of observation. For example, if policies enacted in one country are influenced by policy choices in other countries, then they are said to spatially depend on each other. From a theoretical perspective, spatial dependence can result from pressure, externalities, learning and emulation.⁴ The major destination countries of internationally trafficked persons are likely to exert pressure onto countries which function as major sources of transit and/or origin for people trafficked into these major destinations. Major destination countries will be

⁴ See Elkins and Simmons (2005) for a summary overview of causal mechanisms of spatial dependence (which have to a greater or smaller extent already been extensively discussed in the spatial econometric literature since its beginnings). Elkins and Simmons list coercion, rather than pressure, and add competition. However, strictly speaking coercion is incompatible with policy choice and competition can be subsumed under externalities. On the other hand, emulation could be subsumed under learning unless countries blindly follow others in their policy choices.

averse to illegal migration into their territories (as international trafficking always is) and will resent the increase in other transnational criminal activities (such as drug and arms trafficking) that typically accompany human trafficking. Moreover, human trafficking creates a shadow economy of illegal labor markets and businesses with estimated annual profits of some one billion dollars in industrialized countries (Belser 2005) – money which is not taxed and is likely to be used for illegal activities. Yet, the effectiveness of policies undertaken in destination countries will be undermined if other countries, particularly relevant transit and origin countries, do not follow suit. The strictest anti-trafficking policies in destination countries may be ineffective if countries of origin and transit have lax policies in place. Hence, successful anti-trafficking policies in destination countries depend on a ratcheting up of policies in origin and transit countries, as well as major destination countries exerting pressure on laggards.

In addition to pressure, externalities are rampant in this policy area (Simmons and Llyod 2010). Anti-trafficking policies enacted by one country create significant externalities that other countries cannot simply ignore. Stricter policies in one destination country will deflect some of the flows of trafficked persons into other destination countries, while stricter policies in one origin or transit country will prompt transnational trafficking networks to increasingly resort to other origin or transit countries. Similar to international drug-trafficking, unless policies can address the underlying supply and demand factors driving international trafficking (which they typically cannot), stricter anti-trafficking policies in one country will merely deflect the problem onto other countries with weaker policies in place, such that there is an incentive to ratchet policies upwards over time. In other words, by predicting externality effects of such transnational crime, countries will be able to update their anti-trafficking measures, following relevant policy changes of other countries which share certain characteristics, such as geographic proximity and economic similarity.

Lastly, anti-trafficking policies are being set in a relatively new arena of public policies, with some countries, such as the United States and a few countries in Western Europe, running ahead of others. Laggards will be uncertain in regards to which policies to choose on their own, and will therefore look for cues (or information) in the policies of other countries. Importantly, countries will not simply wish to follow the top leaders in North America and Western Europe. These are all major destination countries and following their lead may not produce positive outcomes in other countries – mostly origin and transit countries of trafficking victims – because the root causes of the problem and the groups targeted differ from those of the leading countries as does their cultural and political setting.

In dealing with uncertainty regarding policy design and its outcomes, the more competently governed lagging countries will want to actively learn from leaders in their *reference* groups – i.e., from culturally, politically, or geographically proximate countries who are also early adopters of relevant policies (Elkins and Simmons 2005), while other laggards may simply wish to emulate or mimic policies from other reference countries without any major learning effect.

In sum, there are many reasons why one would expect spatial dependence in anti-trafficking policies. Some countries will be pressured by others, some will experience externalities created by others, and some will want to learn from or emulate others. Importantly, the strength of these effects will differ across countries, depending on how and to whom they are connected. To test for these hypothesized spatial dependence effects, we estimate spatial autoregressive models in section 5, in which the spatially-weighted policy choices of other countries are allowed to affect the domestic policy choice of the country under observation, with the weights capturing the various types of connectivity among countries. Before discussing our empirical research design, we explain how we have coded novel measures of anti-trafficking policies.

3. Novel Measures of Anti-trafficking Policies

In response to the emergence of human trafficking onto the international policy arena, several important international legal instruments have been introduced in the past ten years, including the *United Nations Convention against Transnational Organized Crime* and its *Protocol to Prevent, Suppress and Punish Trafficking in Persons, especially Women and Children* (2000) and the *Council of Europe Convention on Action against Trafficking in Human Beings* (2008).⁵ The adoption of the Convention and the Protocol is followed by rapid ratification by countries. After opening for signature in November 2000, the Convention has been ratified by 158 parties and the Protocol by 142 to date. The Protocol in particular represents an important step forward, by providing an internationally recognized definition of human trafficking⁶ for

⁵ There are several earlier versions of international treaties for human trafficking, including the International Agreement for the Suppression of the "White Slave Traffic" (1904). Several other international treaties relevant to human trafficking exist today: The International Labor Organization Convention 182, the Elimination of Worst Forms of Child Labor (1999); the United Nations Optional Protocol to the Convention on the Rights of the Child on the Sale of Children, Child Prostitution and Child Pornography (2000); the International Labor Organization Convention 29, Forced Labor (1930); and the International Labor Organization Convention 105, Abolition of Forced Labor (1957).

⁶ According to the Anti-trafficking Protocol, *trafficking in persons shall mean the recruitment, transportation, transfer, harboring or receipt of persons, by means of the threat or use of force or other forms of coercion, of abduction, of fraud, of deception, of the abuse of power or of a position of vulnerability or of the giving or receiving of payments or benefits to achieve the consent of a person having control over another person, for the*

the first time, as well as introducing its three important policy dimensions: (i) prosecuting (criminalizing) traffickers, (ii) protecting victims, and (iii) preventing the crime of human trafficking (UNODC 2006).

Our novel and original indices are coded to reflect policies in these three dimensions. We decompose each dimension into several important requirements prescribed by the Protocol and evaluate compliance for each of them. Compliance with these requirements is independently evaluated by at least two trained coders based on clearly instructed coding guidelines and decision rules.⁷ The scores for each dimension are aggregated to a five-point scale ranging from 1 to 5, where the highest value indicates full compliance and the lowest value no compliance.⁸

The raw data are derived from two reports on human trafficking, the Annual Report of Trafficking in Persons (United States State Department, 2001-2010) and the Report on Trafficking in Persons: Global Patterns (United Nations Office on Drugs and Crime, 2006 and 2009). The U.S. State Department reports provide detailed country narratives every year on the anti-trafficking efforts of up to 180 countries in the three dimensions of human trafficking listed above (an annual report covering the period one year before publication). The UN Office on Drugs and Crime reports include information about criminal justice and victim protection policies in approximately 155 countries for various years.⁹ As the State Department's reports provide systematic and comprehensive information covering a larger number of countries each year, we use these as our main source. We then check the validity of the information provided by employing the UN reports.

The sub-index on 'prosecution policy' measures the level of governments' efforts to punish and prosecute traffickers and other related offenders (such as employers of trafficking victims, law enforcement officials who collude with traffickers, and clients of services provided by human trafficking victims). The prime requirements for governments to implement are broken down into six areas: (i) the adoption of anti-trafficking law, (ii) the adoption of child trafficking law, (iii) the application of other relevant laws, (iv) the stringency of penalties, (v) the level of law enforcement, and (vi) the collection of crime statistics. We select these requirements based on article 5 (criminalization) of the Protocol.

purpose of exploitation. Exploitation shall include, at a minimum, the exploitation of the prostitution of others or other forms of sexual exploitation, forced labor or service, slavery or practices similar to slavery, servitude or the removal of organs (article 3-(a)).

⁷ Appendix 1 presents a short version of the coding guidelines. The full version is available in our online appendix (www.human-trafficking-research.org).

⁸ In the rare case of disagreement between the two coders, the principal investigators decided on the scores.

⁹ The reports summarize information about the adoption and implementation of anti-trafficking policies from the 1990s to the present, but do not provide systematic information on an annual basis.

Countries receive the highest possible score (five) if the country has a legislative measure specifically prohibiting trafficking in persons and the law is fully enforced. It receives a score of four if it has adopted legislative measures specifically prohibiting trafficking in persons but the law is not fully enforced. A score of three is coded if the country does not have a legislative measure specifically prohibiting trafficking in persons but applies some other relevant laws to punish offenders and this other law is at least adequately enforced. A score of two implies that the country does not have a legislative measure specifically prohibiting trafficking in persons, but it applies some other related law to punish offenders without, however, adequately enforcing this law. If the country has a legislative measure specifically prohibiting trafficking in persons but does not enforce the law at all it also receives a score of two. The lowest possible score of one is obtained if the country does not have a legislative measure prohibiting trafficking in persons, no other law is applied, and there is no evidence of punishment for such a crime at all. The short description of the coding guideline is reproduced in Appendix A and the detailed full version is available in our online appendix.¹⁰

The second sub-index, ‘protection policy’, is coded analogously. It assesses the level of governmental efforts to protect and assist the victims of human trafficking. Nine prime requirements imposed by the Protocol (article 6, 7 and 8) are evaluated: (i) no punishment of victims, (ii) imposing no self-identification in order to prove their status as a victim; (iii) assistance for legal proceedings, (iv) the provision of residence permits, (v) basic services for housing, (vi) medical training, (vii) job training, (viii) assistance for rehabilitation and (ix) assistance for repatriation. Ensuring no punishment of victims receives special consideration in our evaluation¹¹ because this requirement represents a basic human right in anti-trafficking policy, recognizing ‘victims of exploitation’ (UNODC 2006; Cameron and Newman 2008: Chapter 1). The highest score of five is given to countries demonstrating very strong efforts in preventing trafficking in persons. Countries obtain a score of four (three) if they demonstrate strong (modest) efforts against trafficking in persons, and a score of two for limited efforts. A score of one is given if the country demonstrates no effort against trafficking in persons. Again, the coding guidelines are provided in Appendix A and the online appendix.

The third dimension of anti-trafficking policies, ‘prevention policy’, evaluates the level of governmental efforts to prevent and combat human trafficking. Based on the requirements of the Protocol provided in article 9, 10, 11, 12 and 13, seven areas are evaluated. Examples are the implementation of campaigns for anti-trafficking awareness;

¹⁰ See www.human-trafficking-research.org.

¹¹ To obtain score 4 or 5, the requirement of no punishment of victims has to be satisfied.

training government and military officials (including peace keepers); facilitating information exchange among relevant authorities; monitoring borders, train stations, airports, etc.; adopting national action plans for combating trafficking in persons; promoting cooperation with NGOs and international organizations; and facilitating cooperation with other governments. Again, the index ranges between one and five, with higher values reflecting stricter policies, as detailed in Appendix A.

In addition to the three sub-indices, we also calculate an overall “3P” anti-trafficking policy index. This is computed as the unweighted sum of the three dimensions. The overall index thus ranges between 3 and 15. It is available for up to 175 countries over the 2000-2009 period. Data availability and global and regional average scores are illustrated for selected years in Table 1. As can be seen, relevant information becomes available for more countries over time. As expected, the developed world performs better than the rest of the world. European and OECD countries demonstrate the highest commitments to anti-trafficking policies in all of the three dimensions, while efforts are minimal and even decreasing in South Asia and the Middle East in recent years.

Table 1 is based on all available information with changing country samples over time. In order to detect policy changes over time, we prefer to fix the sample to those countries that have data available over the entire period of time. This is done in figures 1-3, which illustrate how anti-trafficking policies in different groups of countries develop over time. This graphical illustration shows that the level of compliance in all of the three dimensions improved for the last ten years (see figure 1). In particular, compliance with prosecution policy was highest, on average, for all years and experienced the most significant improvement during the period: In the fixed sample, the worldwide average score of 2.90 in 2000 increased to 4.26 in 2009. Meanwhile, the average prevention policy score increased from 2.53 in 2000 to 3.67 in 2009. On the contrary, our index suggests that governmental efforts to protect victims of human trafficking remain weaker than their efforts to criminalize traffickers and prevent the crime of human trafficking. The worldwide average score of protection policy are lowest for all years, e.g., 2.26 in 2000 and 2.97 in 2009, and also shows the slowest improvement over time. This descriptive outcome of our index indicates that, in terms of compliance with anti-trafficking policy, countries take the ‘justice and prevention’ aspect of the crime more seriously than the human rights aspect, as pointed out by Simmons and Lloyd (2010).

Figure 2 shows the development of the 3P index across regions over time, while figure 3 contains the same information for different income groups. As can be seen, with the exception of the Middle East/North Africa and South Asia, there are clear improvements in

compliance with anti-trafficking policies over time. It is in these regions, together with Sub-Saharan Africa, where the overall level of the anti-trafficking policy index is lowest in 2009. It is also remarkable that the 3P index showed high values in the Western Europe and other industrialized countries group, while the remaining groups converged to this higher level over the 2000-2009 period. Splitting the sample up by income, the index levels are particularly high for OECD countries. High-income non-OECD countries show lower levels of compliance with anti-trafficking policies, comparable to those of low income countries, as well as lower and upper middle income countries. All country groups have improved their index values since 2000.

Table 2 shows that the three dimensions of the 3P anti-trafficking policy index are clearly not redundant. It reports the correlation coefficients across the sub-indices and the overall index, as well as the U.S. Department of State's tier-ranking. Not surprisingly, the three dimensions are positively correlated with each other. However, the correlations among the sub-indices of the 3P index are modest, ranging between 0.52 and 0.64. This suggests that the sub-indices are individually relevant and the disaggregation into the three dimensions captures differences in compliance across countries with each of the 3Ps.¹² The table also shows the modest levels of correlation between each of the 3Ps and the tier-ranking. The correlation of 0.72 between the aggregate 3P index and the tier-ranking suggests that both measures capture the general direction of the development of anti-trafficking policies, but are to some extent different. We stress that compared to the tier-ranking, our index does not rely on a single informational source, but integrates all available information in order to minimize potential biases one informational source may have.

4. Estimation Model, Method and Data

Rather than choosing our own model specification, which might be suspected to have been selected with a view toward producing favorable results on our hypotheses, our baseline estimation model and choice of control variables simply follow the specification in Bartilow (2010). His dependent variable is the level of compliance with the United States 2000 Victims of Trafficking and Violence Protection Act (TVPA). The U.S. Department of State reports a ranking of countries with respect to their actions to fight human trafficking, on a scale of 1-

¹² The usual threshold for regarding sub-dimensions as relevant is a correlation of at most 0.7 (McGillivray and White 1993).

3.¹³ On the original scale, countries whose governments fully comply with the TVPA receive the lowest value (tier 1). Countries with governments not fully complying with the minimum standards required but exerting a significant effort to achieve full compliance, are ranked medium (tier 2), while countries with governments that do not fully comply and do not exert significant efforts are ranked highest (tier 3).¹⁴ We recode the ranking so that higher values are deemed “better.” We use this dependent variable only in a baseline regression for comparative reasons. Our main estimations are based on our newly constructed anti-trafficking policy variables.

Our regressions are based on pooled time-series cross-section (panel) data, covering the 2002-2009 period.¹⁵ We use robust standard errors, clustered at the country level, to account for the fact that observations from the same country in different years are not independent observations. Since some of the data are not available for all countries or years, the panel data are unbalanced and the number of observations depends on the choice of explanatory variables. Still following Bartilow, we include the temporal lag of the dependent variable, which turns out to be highly significant according to all specifications. Our preferred estimation equation takes the following form:

$$y_{i,t} = \alpha + \beta_1 y_{i,t-1} + \beta_2' X_{i,t} + \beta_3 \sum_k \omega_{ik,t-1} y_{k,t-1} + \eta_i + \lambda_t + \varepsilon_{i,t}, \quad (1)$$

where $y_{i,t}$ represents our measures of anti-trafficking policies in country i at year t , $X_{i,t}$ is the vector of explanatory variables, η_i and λ_t represent country and year fixed effects respectively, and $\varepsilon_{i,t}$ represents the idiosyncratic error term. The spatial lag variable $\sum_k \omega_{ik,t-1} y_{k,t-1}$ consists of the product of the ‘spatial y’ and a spatial weighting matrix $\omega_{ik,t-1}$. The spatial y is the value of the dependent variable in other countries k , while the spatial weighting matrix measures the relative connectivity between country i and other countries k (Plümper and Neumayer 2010). We use different weights, as explained below, thus generating different spatial lag variables, which enter separately in the estimation models. The reason for not including them together in our preferred specifications is that the spatial lag variables are highly correlated with each other, thus creating multi-collinearity problems if jointly

¹³ Bartilow (2010) uses a fourth category relying on information on how a country’s policies evolve compared to the previous year (i.e., whether the country is on the “watchlist”). We do not follow this coding, as “tier 2” and “tier 2-watchlist” reflect the same level of compliance.

¹⁴ See the Trafficking in Persons Report (2010), U.S. Department of State.

¹⁵ Data on compliance with human trafficking policies for the years 2000-01 are also available. However, given that values are missing for many countries in these years we exclude them from the analysis.

estimated.¹⁶ Still, we also report results with all spatial lag variables included. We row-standardize all weighting matrices, such that the spatial lag variables represent the weighted average of policies in other countries. This practice, which is typically, if erroneously, regarded as standard practice (Plümper and Neumayer 2010), is nevertheless justified here. Our theory predicts that countries will learn from their civilizational peers and main trading partners, independent of how many peers there are or how much they absolutely trade. With this in mind, row-standardization is appropriate. All spatial lag variables are temporally lagged by one year since it is unlikely that countries could react to the policies of other countries immediately (i.e., in the same year).

The dependent variables are categorical and ordinal, for which in principle ordered probit or ordered logit would be the most appropriate estimators. However, the larger the number of categories, the less persuasive the case for using ordered probit or logit (Wooldridge 2002) and our aggregate 3P index has 15 categories. Moreover, Hausman tests strongly call for the inclusion of country fixed effects to avoid omitted variable bias from unobserved country heterogeneity (see equation (1)), which is facilitated by using a linear estimator like ordinary least squares (OLS) or the system GMM estimator suggested by Arellano and Bover (1995) and Blundell and Bond (1998). We therefore use both ordered probit, OLS and system GMM.

In choosing our control variables, we again follow Bartilow (2010) and include an index of control of corruption. This perceptions-based index is provided by Kaufmann et al. (2009) and ranges from -1.63 (high risk of corruption) to 2.58 (low risk of corruption), in the estimation sample of Table 3, column 1 below.¹⁷ Enforcement of policies is likely to depend on the government and bureaucracy's capacity to enforce these policies. With rising corruption, both bureaucrats and government officials are less likely to enforce sound policies. A lower degree of corruption is thus likely to improve policies against human trafficking. We include the Polity IV indicator of democracy, ranging between -10 and 10, with higher values representing a more democratic political regime (Marshall and Jaggers 2009). This is because democratic governments should be more likely to follow international law (Bjørnskov 2010, Dixon 1993, Hathaway 2007, Neumayer 2005, Slaughter 1995). In democratic countries, it is easier for citizens, non-governmental organizations and the media to monitor governmental compliance with an international treaty. Furthermore, as the democratic legalism literature

¹⁶ In our estimation sample, the correlation of the spatial lags is around 0.5. Note that the significant coefficients might thus to some extent reflect the effects of other, omitted, lags.

¹⁷ Bartilow uses Transparency International's Corruption Perception Index. However, this index does not provide comparable time-series data and substantially reduces the number of observations if included, so we prefer to use the index provided by Kaufmann et al. (2009) here.

suggests, democracies are more likely to comply with international legal obligations because of their respect for judicial processes and constitutional constraints carried over into the realm of international politics (Simmons 1998). According to Bartilow, gender representation is important for human trafficking policies. As he argues, women are more likely to pursue policies which protect their own rights.¹⁸ We measure the level of women's rights employing two indicators: The percentage of female parliamentarians in the national parliament (taken from the World Bank Gender Statistics 2010) and the Cingranelli-Richards indicator of women's economic rights.¹⁹ We code an International Regime dummy variable, using data on whether or not a country has ratified the United Nations Protocol to Prevent, Suppress and Punish Trafficking in Persons, especially Women and Children (2000). Finally, we include a country's (log) per capita GDP and the amount of U.S. aid inflows (as a percentage of GDP). While per capita GDP proxies for a country's level of development, U.S. aid measures the potential pressure exerted by the U.S. to reform policies. Indeed, the U.S. State Department sometimes threatens to withhold aid in case of non-compliance with human trafficking policies (U.S. Department of State, Annual Report on Trafficking in Persons 2004).²⁰ In section 2, we identified pressure as one of the reasons for spatial dependence in anti-trafficking policies. The inclusion of the U.S. aid measure is meant to capture any pressurizing effect that the U.S. might exert on aid-receiving developing countries, such that our spatial lag variables, to which we turn now, do not simply pick up the effect that U.S. pressure has on policies in the main recipient countries of its aid.

As argued in section 2, when choosing anti-trafficking policies, countries are very likely to spatially depend on the policy choices of other countries. Such spatial dependence is best analyzed in what is called a spatial autoregressive model, in which the weighted average of the dependent variable in other countries (the so-called spatial lag variable), enters the estimation equation as an explanatory variable. The weights used in the construction of the

¹⁸ This is in line with the broader literature. For example, according to Chattopadhyay and Duflo (2005), reservation of political mandates for women in India has led to policies benefiting especially women. Studying voting behavior of U.S. congressmen, Washington (2006) finds that congressmen with daughters are substantially more likely to vote in-line with feminist views.

¹⁹ Bartilow uses a narrower indicator on gender equality of marriage and divorce, while we prefer to use an indicator more broadly defined. Using the CIRI indicator of women's social rights, we lose more than 400 observations, so we prefer taking the economic rights indicator. Correlation between the two among our sample is 0.64.

²⁰ Bartilow (2010) uses the absolute amount of U.S. aid. We prefer to scale inflows by GDP in order to avoid capturing a mere scale effect. We also included the share of women among the ministers of a country's government (taken from various issues of the UNDP Human Development Reports). Given that these data are only available for four years, we had to use linear interpolation before being able to include the variable in the regression. Note however, that the share of female ministers is not significant at conventional levels in any of the specifications shown in Table 3. Bartilow also uses some additional variables that did not turn out to be significant at conventional levels in his regressions. We do not include them here.

spatial lag variable represent the relative importance of foreign countries' policy choices for domestic policy-making in the country of observation. Weights can be dichotomous, as is the case with the dummy variables for the location of countries in a certain region or the sharing of a common border between countries, or continuous, as is the case for the variables measuring the spatial proximity between countries or the importance of their trade relationship.

In section 2, we identified pressure, externalities, learning and emulation as reasons for spatial dependence in anti-trafficking policies, i.e., as causal mechanisms or channels through which policies might diffuse. Unfortunately, it is not possible to choose weights that either perfectly or exclusively capture one of these diffusion channels. However, our weights were chosen with a view to account for these channels as much as possible. Specifically, as weighting variables we use information on the identity of the major transit and source countries for each destination country, contiguity (two countries share a land border or are separated by less than 150 miles of sea distance), bilateral trade, similarity in voting on those issues regarded as key by the United States in the United Nations General Assembly,²¹ and a civilizational dummy. Transit and source countries are vulnerable to pressure from their major destination countries since the effectiveness of policies in the latter requires the ratcheting-up of policies in the former. Note that in the estimations containing this spatial lag variable, the sample is reduced to countries which function as major transit or origin countries as we assume that these countries experience pressure from destination countries. The relevant spatial lag variable is undefined for countries that do not fall into this category. Contiguity and bilateral trade predominantly capture externalities. A country contiguous to other countries k is likely to experience the strongest impact of any externality generated by policy choices in countries k . This is because contiguous countries tend to be close substitutes as either destination, transit or origin countries. The same is true for countries which trade a lot with each other, not least because flows of people often follow flows of goods and services. Of course, contiguity and bilateral trade do not exclusively capture externality effects, but will also partly cover learning and emulation effects if countries learn from or emulate those countries of geographical proximity or economic importance. To some extent, due to the correlation among the spatial lags they will in part also capture the impact of the omitted lags.

²¹ Not all votes in the General Assembly are likely to be of great importance. Focusing on a sub-set of votes might thus be superior. The U.S. State Department provides a classification of votes it considers important in yearly reports since 1983. Arguably, these votes are also likely to be the more important ones (on average) for countries other than the United States. The voting behavior of each country on every roll call vote in the UN General Assembly since 1946 has been documented by Voeten and Merdzanovic (2008), and revised by Kilby (2009).

Yet, we argue that similarity of voting and the civilizational belonging of countries predominantly capture learning and emulation effects. Countries wishing to learn from or emulate other countries will seek those with which they share common political views and/or values. The similarity of voting in the UN General Assembly, particularly on key issues, captures the similarity of political views well, while countries belonging to the same civilization, such as the Western, Islamic, African, Latin American, Sinic or Hindu groups, are likely to share common values.

Appendix B shows the exact definitions of all variables with their sources, while Appendix C reports descriptive statistics.

5. Results

Column 1 of Table 3 replicates the analysis of Bartilow (2010) for our sample and definition of explanatory variables. The dependent variable is the 3-scale tier ranking provided by the U.S. Department of State. Given the ordinal nature of the dependent variable, estimation is carried out with ordered probit. We therefore omit the country fixed effects because including country dummies in ordered probit/logit models with a limited number of observations tends to produce inconsistent estimates – the so-called incidental parameter problem (for a summary see Lancaster 2000). We do however include a dummy for each year.

As can be seen in column 1, the quality of a country's anti-trafficking policy improves with the perceived absence of corruption and a more democratic regime, at the one and five percent levels of statistical significance, respectively. At the ten percent level, better women's rights on the CIRI indicator are correlated with stricter policies against human trafficking. The lagged dependent variable is also significant at the one percent level, with the expected positive coefficient. Contrary to the results in Bartilow, per capita GDP, U.S. aid, and international regime membership are not significant at conventional levels.²²

Column 2 replicates the analysis using our overall 3P index as the dependent variable instead. As can be seen, the results are largely unchanged. The exception is the control of corruption index, which turns out to be insignificant at conventional levels.

Given that our 3P index contains 15 categories, OLS seems suitable as well. Given that it also eases the quantitative interpretation of the coefficients, we report OLS results in columns 3 and 4. While column 3 excludes country fixed effects, column 4 includes them. Excluding fixed effects, the results are almost identical to the ordered probit specification.

²² Note however that Bartilow uses instrumental variables to take account of the potential endogeneity of U.S. aid. Given that this variable is not central to our analysis, we do not follow Bartilow here, but acknowledge the likely endogeneity of the variable.

However, once we include them, the control of corruption index is significant at the five percent level, while the share of women in the legislature is no longer significant at conventional levels. Surprisingly, the coefficient of democracy reverses its sign, but is only significant at the ten percent level.

With the temporally lagged dependent variable and the country fixed effects simultaneously included in the estimations, our results could be biased and inconsistent in a short panel (Nickell 1981). We therefore proceed with the system GMM estimator as developed in Arellano and Bover (1995) and Blundell and Bond (1998). Results are based on the two-step estimator implemented by Roodman (2005) in Stata, including Windmeijer's (2005) finite sample correction. The Hansen test on the validity of the instruments used (amounting to a test for the exogeneity of the covariates), and the Arellano-Bond test of second order autocorrelation (which must be absent from the data in order for the estimator to be consistent), do not reject the specification at conventional levels and thus support our choice of which variables to model as exogenous.

The results from column 5 are similar to those obtained previously with ordered probit and OLS (excluding country fixed effects). In columns 6 and 7 we replicate the results excluding the three variables that are never significant at conventional levels (international regime membership, per capita GDP and U.S. aid). The results are unchanged.

Quantitatively, we find that an increase in the democracy index by one point increases the 3P index by 0.07 points, while an increase in the women's rights index by one point increases it by 0.24 points (focusing on the GMM results reported in column 7). An increase in control of corruption by 0.1 on the -1.6 to 2.6 scale, increases the 3P index by almost 0.04.

In Table 4 we turn to the estimation of our hypothesis of spatial dependence in anti-trafficking policies, initially focusing on the aggregate 3P anti-trafficking policy index. The identification of a spatial dependence effect rests on the assumption that the estimation model controls for confounding factors that may be correlated with the spatial lag. This is a demanding requirement. If, for example, policies generally become more stringent over time, then spatial lag variables will tend to be statistically significant predictors, but unless the general upward trend in policies is truly caused by spatial dependence, the estimated coefficient is upward biased. Similarly, although countries may make similar policy choices because of shared values or cultures predominating in a region for example, this doesn't necessarily mean that any true spatial dependence effect is at work via learning or emulation. Plümper and Neumayer (2010) argue that one must include the temporally lagged dependent variable and year-specific time fixed effects to account for common trends over time and

common temporal shocks, while country fixed effects are needed to account for unobserved spatial heterogeneity and the spatial clustering of countries. Such stringent model specification minimizes, but cannot fully eliminate, the impact of potentially confounding factors. Fortunately, this model specification coincides with our preferred estimation equation (1). Spatial lag variables cannot be exogenous: If country i were to be affected by the policies of other countries, the policies of other countries will also be affected by the policies chosen by country i . Rather than applying spatial maximum likelihood techniques, which are computationally difficult to implement, in Table 4 we exclusively use the system GMM estimator, additionally modeling the spatial lag variables as endogenous, similar to the temporally lagged dependent variable. Kukenova and Monteiro (2009) show that in Monte Carlo simulations, the system GMM estimator outperforms other estimators for spatial dynamic panel data models with one or more endogenous variables. For parsimony, we focus on the model specification from column (7) in Table 3.

As can be seen in Table 4, the effects of the control variables are not greatly affected by the inclusion of the spatial lags. Two of the spatial lags are significant at the five percent level at least, those being the contiguity and voting similarity-weighted ones. As argued above, this most likely captures an externality and a learning or emulation effect. Contiguous countries are exposed to the effect of stricter policies in neighboring countries,²³ while countries look for cues from other countries with similar political views in their own policy design. In contrast, we find no evidence of a pressure effect since origin and transit countries do not seem to follow the policies of the countries for which they are major countries of transit or origin. If other contiguous countries increased the strictness of their anti-trafficking policies by one point in the previous year, then the country under observation is estimated to tighten its own policy by 0.232 points. In other words, the (short-run) speed of policy diffusion is about one quarter. The speed of policy diffusion is stronger for the spatial dependence effect, which weighs the influence of other countries by the degree to which they vote similarly on key issues at the UN General Assembly. A one point tightening of policies in similar countries in the previous year raises domestic policy stringency by roughly half a point. Note that the sum of the coefficients of the spatial lag and the lagged dependent variable exceed unity in column (4) and some other model specifications reported in the following tables. This would imply an explosive process if interpreted as a non-changing long-run relationship. However, in the context of the limited time-series we focus on, the sum

²³ We alternatively weighted anti-trafficking policies with distance rather than contiguity. The resulting coefficient is not significant at conventional levels. This would suggest that the externality-effect is concentrated on geographically proximate countries, as captured by contiguity, with countries further away having no impact.

of the coefficients does not need to be below unity since diffusion might resemble an explosive process to start with, and then significantly slow down as time passes.²⁴

Column 6 includes the spatial lags jointly rather than separately. In order to minimize the number of instruments in the regressions, we collapse the matrix of instruments as suggested in Roodman (2006), a practice we follow in all other specifications that jointly include all spatial lag variables.²⁵ As can be seen, none of the lags remains significant at conventional levels, even though the insignificance is marginal in most cases. However, the voting-weighted lag remains significant in a specification where we do not collapse the instruments (not shown in the table). Overall, we prefer to rely on the specifications including one spatial lag at the time, but note that the significant coefficients might to some extent reflect the effects of other, omitted, lags.

In Table 5 we focus on the individual dimensions of the 3P index, starting with model specifications excluding the spatial lag variables. Estimation is done with GMM, despite the ordinal nature of the five-scale variables. This is because the problem of endogeneity is arguably more important than ignoring the ordinal nature of the dependent variables, in particular when we include the spatial lag variables below.²⁶ We report specifications both including GDP per capita and U.S. aid and excluding them. Note that the Arellano-Bond test rejects the regressions focusing on the prosecution index (columns 3 and 4). We therefore include the second lag of the dependent variable (in columns 5 and 6). This specification is not rejected at conventional levels.

According to the results, GDP per capita and U.S. aid are not significant determinants of either of the constituent dimensions of anti-trafficking policies at conventional levels. The results for the remaining control variables are similar compared to the overall index. The lagged dependent variable is significant at the one percent level throughout. Control of corruption improves prevention and protection policies, but not those relating to prosecution. When controlling for the second lag of the dependent variable in the prosecution regressions, the same holds for democracy. Prevention and prosecution policies improve with better economic rights of women, at least at the ten percent level, but not with the share of women in the legislature, while the reverse holds for protection policies.²⁷

²⁴ Coefficients of similar size are commonly reported in the recent literature (e.g., Gassebner et al. 2011). In an analysis of the spread of corporate responsibility standards, Perkins and Neumayer (2010) find that an explosive diffusion process in a short panel turns into a non-explosive process when a panel of longer duration is analyzed.

²⁵ It is necessary to limit the number of instruments because the power of the Sargan-Hansen test is low when many instruments are used (Bowsher 2002). Moreover, too many instruments might cause an overfitting of the instrumented variable.

²⁶ This is common in the recent literature (e.g., Dreher et al. 2010).

²⁷ Note however that the Hansen test is borderline in columns (7) and (8).

Tables 6 and 7 include the spatial lags to the parsimonious specifications. The results for prevention and protection policies are reported in Table 6, those for prosecution policies are shown in Table 7 (again including and excluding, respectively, the second lag of the dependent variable). Results for prevention policies are similar to those of the 3P aggregate policy measure when we include the spatial lags individually (columns 1-5). In addition, there is evidence that countries follow policies of those belonging to the same civilizational group, arguably because of learning or emulation effects. When we include the spatial lags jointly (in column 6), only the voting-weighted lag remains significant at the ten percent level. Results on protection policies are striking in that all evidence for spatial dependence has disappeared, with the exception of the voting similarity weighted spatial lag variable (this holds when including the spatial lags individually and jointly). Interestingly, the impact of the contiguity-weighted spatial lag variable is essentially zero. This is exactly what one would expect if our argument that contiguity captures an externality effect is correct. Stricter prevention and prosecution policies deflect flows of trafficked people onto other countries, thus generating an externality, however better victim protection policies do not deflect flows onto others – in fact, the opposite may even be the case, as we argued in the introduction.

Results on prosecution policies confirm that countries follow the policies of contiguous countries. When including the spatial lags separately, countries also seem to follow the policies of their major trading partners. Countries do not seem to follow policies of politically similar countries, as measured by the voting similarity weighting variable, but follow policies of countries belonging to their own civilization. As was the case before, we find no evidence for diffusion of policies via pressure from destination countries on their major transit and source countries (the relevant spatial lag is marginally significant in column (1), but insignificant if the second temporal lag of the dependent variable is included (as is required according to the result of the Arellano-Bond test). In the specification that includes all spatial lag variables, we even find a negative coefficient of the traffic link weighted spatial lag. This points toward a potential substitution effect: Stricter prosecution policies in destination countries would allow relevant major transit and origin countries to relax their prosecution policies, knowing that perpetrators are more strongly prosecuted elsewhere.

6. Robustness Tests

Finally, we perform two important robustness tests. First we estimate regional jackknife analyses, in which all countries of one particular region are dropped from the analysis at the time in order to test whether the results are driven by the presence of observations from a

specific region in the sample.²⁸ Note that the spatial lags in these estimations are still based on the global sample, as taking out specific regions from the creation of the spatial lag variables would amount to mis-specification. The results shown in Tables 8 and 9 are based on model specifications that include each spatial lag variable on its own. Starting with overall anti-trafficking policies in the upper part of Table 8, we find that the contiguity and voting-weighted spatial lag variables remain statistically significant independent of the region dropped from the sample. Strikingly, as the results reported in column 1 show, there is much more evidence for spatial dependence in anti-trafficking policies in developing countries. If the developed countries are dropped from the sample, there is additional evidence of anti-trafficking policies diffusing via trade links and civilizational similarities. For prevention policies, the contiguity and voting-weighted spatial lags remain statistically significant at conventional levels in most jackknife specifications, but it is only diffusion via reference to countries that belong to the same civilization for which there is almost consistent evidence, with the exception of the model excluding countries from North Africa and the Middle East.²⁹

For protection policies, the regional jackknife estimation results reported in the upper part of Table 9 suggest that the voting-weighted spatial lag variable is a robust predictor. There is again some evidence for diffusion via civilizational belonging, but the respective spatial lag variable is only significant in three out of seven estimations. Results for prosecution policies largely confirm the existence of spatial dependence working via contiguity, trade and civilizational links. Interestingly, in two cases we find again negative coefficient signs for the traffic link-weighted spatial lag variable, which we found already in table 7, but only for the specification that included all spatial lag variables simultaneously. This suggests that the effect reported for table 7 was not entirely due to multi-collinearity problems. Dropping either Eastern and Central European or Sub-Saharan African countries from the sample, we find that stronger prosecution policies in destination countries have a negative (or substitution) effect on prosecution policies in major transit and origin countries, such that the latter relax their own policies knowing that perpetrators are more vigorously prosecuted in destination countries. This result is not robust to other model specifications and we do not want to make too much of it, but we regard this as one of the findings that deserves closer attention in future research.

²⁸ We also examined the robustness of our results to the exclusion of countries where neither major flows of human trafficking originate from nor, respectively, go to. In both sets of regressions the t-statistics are lower compared to those reported above, but the results are generally similar. All results will be made available in the replication data.

²⁹ Note that the specification excluding the Middle East and North Africa suffers from a potential endogeneity problem, the p-value of the Hansen test being 0.09, while the Hansen tests in all other samples do not reject the specifications at conventional levels of significance.

Next we turn to the robustness of our results to the choice of control variables. As the theory and empirics of anti-trafficking policies have only begun to be seriously addressed recently, there is still considerable uncertainty about which explanatory variables to include. To examine the sensitivity of the results reported above, we therefore employ (variants of) the extreme bounds analysis (EBA), as proposed by Leamer (1983) and Levine and Renelt (1992), as our second test for robustness. EBA enables us to examine whether the spatial lags are indeed robust determinants of anti-trafficking policies, independent of which additional variables are also included in the set of control variables.

To conduct an EBA, equations of the following general form are estimated:

$$y_{i,t} = \beta_M M + \beta_F F + \beta_Z Z + v, \quad (2)$$

where $y_{i,t}$ again represents our measures of anti-trafficking policies in country i at year t , M is a vector of “commonly accepted” explanatory variables and F is a vector containing the variables of interest (i.e., each spatial lag on its own). The vector Z contains up to three possible additional explanatory variables (as in Levine and Renelt 1992), which, according to the broader literature, are related to the dependent variable. The error term is v .

The EBA-test for a variable in F states that if the lower extreme bound for β_F — i.e., the lowest value for β_F minus two standard deviations — is negative, while the upper extreme bound for β_F — i.e., the highest value for β_F plus two standard deviations — is positive, the variable F is *not* robustly related to anti-trafficking policies.

Sala-i-Martin (1997) argues that this criterion is far too restrictive for any variable to pass the test. If the distribution of the parameter of interest has both positive and negative support, then a researcher is bound to find at least one regression model for which the estimated coefficient changes sign if enough regressions are run. Consequently, not only do we report the extreme bounds, but also the percentage of the regressions in which the coefficient of the variable F is statistically different from zero at the five percent level.

Moreover, instead of merely analyzing the extreme bounds of the estimates for the coefficient of a particular variable, we follow Sala-i-Martin’s (1997) recommended procedure and analyze the entire distribution. Accordingly, we also report the unweighted parameter estimate of β_F and its standard error, as well as the unweighted cumulative distribution function, $CDF(0)$. The latter represents the proportion of the cumulative distribution function lying on each side of zero. $CDF(0)$ indicates the larger of the areas under the density function (either above or below zero). Therefore, $CDF(0)$ always lies between 0.5 and 1.0.

The vector M contains the same variables as the regressions in the tables above. In accordance with the previous literature, to test for the robustness of our results we have collected a total of 14 additional variables which could potentially influence the level of anti-trafficking policies. All variables and their sources are listed in Appendix B.

Our choice of variables follows the three most recent papers on the determinants of anti-trafficking policies (Avdeyeva 2010; Bartilow 2010; Simmons and Lloyd 2010). As Bartilow (2010) and Simmons and Lloyd (2010) argue, a generally well-developed legal system and the enforcement of the law can be an important determinant of the adoption and implementation of anti-trafficking laws. We therefore use the rule of law indicators provided by the ICRG, as well as the World Bank Governance Indicators, to test for the robustness of our results.

According to Bartilow, women's social rights can further capture the gender dimension of human trafficking, while Simmons and Lloyd point out that worker's rights are a good indicator of a country's tolerance of exploitative, forced labor.³⁰ As the issue of human trafficking can be brought into the public spotlight through the media, the level of media freedom, measured by Freedom House, has the potential to influence relevant policy operations (Simmons and Lloyd). Membership in a prestigious club can also explain the compliant behavior of certain countries, in terms of their concern for their reputation. We therefore include a dummy for EU membership, following Avdeyeva (2010). The degree of economic, social and political globalization, measured by the KOF Index of Globalization (Dreher et al. 2008), may also capture associations between the spread of anti-trafficking policies and countries' economic, social and political exposure to the world. This is broadly suggested by Avdeyeva (2010) and Simmons and Lloyd (2010). Inflows of remittances (as a percentage of GDP) can indicate the economic interests a country may have in sending its nationals abroad to work (Simmons and Lloyd). Furthermore, we add those variables already included in Table 3, but excluded from later tables due to their insignificance: (log) per capita GDP, the amount of U.S aid inflows (as a percentage of GDP) and protocol ratification.

The results for the EBA models are presented in Table 10. Following Sala-i-Martin, we use a CDF(0) value of 0.90 as the threshold above which we consider variables to be robust.³¹ We report the results in four panels, one for each dependent variable. The upper-left

³⁰ Both dimensions are measured with data taken from Cingranelli and Richards (2008).

³¹ Sala-i-Martin (1997) proposes using the (integrated) likelihood to construct a weighted CDF(0). However, the varying number of observations in the regressions due to missing observations in some of the variables poses a problem. Sturm and de Haan (2001) show that as a result this goodness of fit measure may not be a good indicator of the probability that a model is the true model and the weights constructed in this way are not equivariant for linear transformations in the dependent variable. Hence, changing scales will result in rather

panel of Table 8 shows the results for the overall anti-trafficking index. As can be seen, the lagged dependent variable is clearly a robust determinant of current levels, with the CDF(0) being equal to one. Among the control variables, democracy and women's economic rights exceed the critical threshold. In line with Table 4 above, the contiguity-weighted spatial lag turns out to be a robust determinant of anti-trafficking policies, with a CDF(0) of 0.95. The effect of the second spatial lag that was significant in Table 4 – voting-weighted – does not turn out to be a robust determinant of the index when we include the various combinations of the explanatory variables. However, given that the correct model specification is unknown, it is worth noting that the CDF will potentially reflect a combination of correctly specified models and misspecified ones. Moreover, the CDF will also partly reflect models with a lower number of observations due to missing data for some of the explanatory variables. While we can have confidence in the robustness of a variable with a CDF(0) exceeding 0.9, we cannot know for sure whether those below this threshold are truly insignificant predictors of the dependent variable.

The remaining panels of Table 10 test the robustness of the models for the individual dimensions of the anti-trafficking index. In summary, some of our previous results turn out to be robust. Regarding prevention, the civilization-weighted spatial lag is highly robust, while the contiguity and voting-weighted spatial lags are not. With respect to protection, the voting-weighted lag is robust, while for prosecution policies, the contiguity-weighted lag survives the EBA test and the trade-weighted lag is very close to the threshold of a CDF(0) exceeding 0.9. Thus conclusively, we continue to find evidence for spatial dependence in anti-trafficking policies even if the spatial lag variables are subjected to this rather demanding robustness test.

7. Conclusion

In this paper, we have introduced new measures of countries' policies aimed at combating international trafficking in human beings. Our aggregate policy index is fine-grained and based on the consistent coding of a wide range of informational sources, while our disaggregated measures capture the three different fundamental dimensions of anti-trafficking policies, namely prevention, protection and prosecution. Scholars may wish to use the aggregate index if they are interested in overall policies, but we strongly recommend that future research analyzes the different dimensions of overall policies separately and in greater

different outcomes and conclusions. We therefore restrict our attention to the unweighted version. Furthermore, for technical reasons – in particular our unbalanced panel setup – we are unable to use the extension of this approach called Bayesian Averaging of Classical Estimates (BACE) as introduced by Sala-i-Martin, Doppelhofer and Miller (2004).

detail than we could do here. For example, protection policies mainly protect victims, while prosecution policies mainly target the perpetrators. Why countries choose to pursue one type of policy rather than the other deserves closer scrutiny.

Besides introducing novel data to the still recent, yet burgeoning literature on human trafficking, we have also contributed to the analysis of anti-trafficking policies by analyzing the effect of spatial dependence in this policy domain, which the extant literature has so far neglected. Domestic policies, we have argued, will be affected by policies abroad because of pressure, externalities, learning or emulation effects. Our results only partly corroborate these hypotheses. On the one hand, we find no evidence for anti-trafficking policies diffusing via pressure exerted by destination countries onto their major transit or origin countries. Our results suggest that anti-trafficking policies are an area where destination countries seem unwilling, or, even if they are willing, are unable to pressure the countries where the majority of victims of human trafficking come from or are channeled through, to change their policies. On the other hand, we find consistent evidence for externality effects – with the exception of protection policies, for which one would not expect such an effect. We thus find that stricter policies in contiguous countries, or sometimes in major trading partners, are followed by stricter domestic policies as well. The most likely explanation is simple: Stricter policies create negative externalities on neighboring countries and trading partners, exacerbating their problems in dealing with human trafficking as a result. Contiguity and trade might also partially capture learning or emulation channels of diffusion. In fact, we find robust evidence that countries look towards those with similar political views, as proxied by our connectivity variable of voting similarity on key issues in the UN General Assembly. This is also the case for countries sharing similar cultural values, as proxied by our connectivity variable measuring civilizational belonging. All in all, we find robust evidence that countries do not operate in isolation when deciding on anti-trafficking policies, being affected by the prior choices of other countries on which their policy choices spatially depend.

Figure 1. Compliance with anti-trafficking policies (global sample), 2000-2009

Note: The unweighted averages use balanced country samples.

Figure 2: Compliance with anti-trafficking policies across regions and time

Note: The unweighted averages use balanced country samples.

Figure 3: Compliance with anti-trafficking policies across income groups and time

Note: The unweighted averages refer to balanced country samples.

Table 1: Global and Regional Average Scores of 3Ps (2000, 2005 and 2009)

	Prosecution			Protection			Prevention			Aggregate 3Ps		
	2000	2005	2009	2000	2005	2009	2000	2005	2009	2000	2005	2009
Worldwide	2.89 (81)	3.55 (159)	3.76 (177)	2.24 (78)	2.79 (156)	2.78 (176)	2.49 (78)	3.19 (159)	3.28 (176)	7.58 (74)	9.61 (156)	9.85 (175)
East Asia / Pacific	2.63 (8)	3.33 (12)	3.76 (17)	2.25 (8)	2.33 (12)	2.29 (17)	2.71 (7)	2.83 (12)	2.76 (17)	7.71 (7)	8.50 (12)	8.82 (17)
Eastern Europe / Central Asia	2.70 (17)	4.50 (24)	4.67 (24)	1.63 (16)	2.82 (23)	3.17 (24)	2.19 (16)	3.42 (24)	3.50 (24)	6.40 (15)	11.0 (23)	11.3 (24)
Latin America / Caribbean	3.44 (9)	3.48 (23)	3.96 (25)	2.22 (9)	2.78 (23)	3.17 (24)	2.5 (8)	2.96 (23)	3.21 (24)	8.13 (8)	9.22 (23)	10.6 (23)
Middle East / North Africa	1.41 (2)	2.50 (12)	2.58 (12)	1.50 (2)	1.83 (12)	1.32 (12)	2.00 (2)	2.25 (12)	2.25 (12)	5.50 (2)	6.58 (12)	6.25 (12)
Western Europe / OECD	3.30 (23)	4.02 (42)	4.17 (48)	2.50 (22)	3.31 (42)	3.25 (48)	2.91 (23)	3.64 (42)	3.77 (48)	8.67 (21)	11 (42)	11.2 (48)
South Asia	3.6 (5)	4.33 (6)	3.43 (7)	2.6 (5)	2.50 (6)	2.00 (7)	2.4 (5)	3.17 (6)	3.00 (7)	8.6 (5)	10 (6)	8.43 (7)
Sub-Saharan Africa	2.25 (16)	2.79 (38)	3.02 (42)	2.47 (15)	2.72 (36)	2.50 (42)	2.19 (16)	3.10 (38)	3.14 (42)	6.87 (15)	8.78 (36)	8.66 (42)

Notes: Number of countries in parentheses.

Table 2: Correlation across prosecution, protection, prevention and the tier-ranking

	Prosecution	Protection	Prevention	Aggregate 3P	Tier-ranking
Prosecution	1.00				
Protection	0.51	1.00			
Prevention	0.52	0.64	1.00		
Aggregate 3P	0.83	0.85	0.84	1.00	
Tier-ranking	0.53	0.63	0.66	0.72	1.00

Note: A lower tier-ranking score reflects better compliance on the original scale, so we reverse the scale here.

					civilization-weighted	0.11	0.10	0.37	0.81

Notes: All results are based on 469 regressions. 'Avg. beta' reports the average coefficient while 'Avg S.E.' indicates the average standard error of all regressions. '%Sig' shows the percentage of regressions in which the coefficient is statistically different from zero at the 5 percent level at least. 'CDF-U' shows the (unweighted) mass of the larger part of the distribution of the estimated coefficients (i.e., the value is always greater or equal to 0.5). The criterion for a variable we consider as robust is a value of 0.9 or above.

Appendix A: Anti-trafficking Policy Index Coding Guideline

(The full-version is available in the online appendix at www.human-trafficking-research.org)

1. Prosecution

Coding Scheme

In measuring government prosecution policy, our primary interests are: 1) whether the country has legislative and other measures to establish criminal offences for trafficking in persons, in line with the definition provided by the Anti-trafficking Protocol; and 2) whether such legislative and other measures are appropriately and effectively enforced.

Score 5:

The country has a legislative measure specifically prohibiting trafficking in persons and; the law is fully enforced in the form of investigations, prosecutions, convictions and punishment of such offenders. Generally, the country should maintain a stringent level of penalty (either more than five years imprisonment or punishment equivalent to other related crimes such as rape or labor exploitation).

Score 4:

The country has a legislative measure specifically prohibiting trafficking in persons; BUT the law is not fully enforced in the form of investigations, prosecutions, convictions and punishment of such offenders.

Score 3:

The country does NOT have a legislative measure specifically prohibiting trafficking in persons; but applies some other relevant laws (such as laws against rape, slavery, exploitation, abuse or human rights violation) to punish offenders of such crimes; and the law is fully or adequately enforced in the form of investigations, prosecutions, convictions and punishment of such offenders.

Score 2:

The country does NOT have a legislative measure specifically prohibiting trafficking in persons; BUT applies some other related law to punish offenders of such crimes; the law is not adequately enforced in the form of investigations, prosecutions, convictions and punishment of such offenders. If the country has a legislative measure specifically prohibiting trafficking in persons but does not enforce the law at all (or there is no evidence that the country has conducted prosecution or conviction of such offenders), it also receives score 2.

Score 1:

The country does NOT have a legislative measure prohibiting trafficking in persons and no other law is applied; and there is no evidence of punishment for such a crime at all.

2. Protection

Coding Scheme

In measuring government protection policy, our primary interests are: whether the country protects the human rights of victims of trafficking; identifies them; and provides for the physical, psychological and social recovery of victims of trafficking by legislative and other measures.

Score 5:

The country does not punish victims of trafficking for acts related to the situations being trafficked; does not impose the self-identification of victims; and exerts **STRONG** efforts to give victims information on, and assistance for, relevant court and administrative proceedings, as well as support for the physical, psychological and social recovery of victims such as housing (shelter), medical assistance, job training, (temporal) residence permit, and other assistance for rehabilitation and repatriation.

Score 4:

The country does not punish victims of trafficking for acts related to the situations being trafficked; does not impose the self-identification of victims; and exerts **MODERATE** efforts to give victims information on, and assistance for, relevant court and administrative proceedings, as well as support for the physical, psychological and social recovery of victims such as housing (shelter), medical assistance, job training, (temporal) residence permit, and other assistance for rehabilitation and repatriation.

Score 3:

The country does not punish victims of trafficking for acts related to the situations being trafficked; does not impose the self-identification of victims; and exerts **LIMITED** efforts to give victims information on, and assistance for, relevant court and administrative proceedings, as well as support for the physical, psychological and social recovery of victims such as housing (shelter), medical assistance, job training, (temporal) residence permit, and other assistance for rehabilitation and repatriation. Or, if the country fails to ensure that victims of trafficking are never punished for acts related to the trafficking itself or the consequences of being trafficking **BUT** exerts **STRONG/Moderate** efforts in protecting victims, the country qualifies for score 3.

Score 2:

The country fails to ensure that victims of trafficking are punished for acts related to the trafficking itself or to the consequences of being trafficked; and there is limited assistance and support for court proceedings and the recovery of victims. Or, the country does not punish victims of trafficking in persons for acts related to the situations being trafficked; however, does not provide any assistance or support for recovery, rehabilitation and repatriation.

Score 1:

The country punishes victims of trafficking in persons for acts related to the situations being trafficked; and does not provide any assistance and support.

3. Prevention

Coding Scheme

In measuring government protection policy, our primary interests are; whether the country establishes and practices comprehensive policies, programs and other measures to prevent and combat trafficking in persons.³²

Score 5:

The country demonstrates VERY STRONG efforts preventing trafficking in persons, such as implementing public and media campaigns for anti-trafficking awareness; training government and military officials (including peace keepers); facilitating information exchange among relevant authorities; monitoring borders, train stations, airports, etc.; adopting national action plans for combating trafficking in persons; promoting cooperation with NGOs and international organizations in the country; and facilitating bilateral and/or multilateral cooperation with other governments.

Score 4:

The country demonstrates STRONG efforts against trafficking in persons, such as implementing public and media campaigns for anti-trafficking awareness; training government and military officials (including peace keepers); facilitating information exchange among relevant authorities; monitoring borders, train stations, airports, etc.; adopting national action plans for combating trafficking in persons; promoting cooperation with NGOs and international organizations in the country; and facilitating bilateral and/or multilateral cooperation with other governments.

³² In evaluating the preventive efforts of governments, we do not include broader developmental measures, such as promotion of education and poverty reduction, in order to distinguish governmental efforts specifically addressed at fighting human trafficking.

Score 3:

The country demonstrates MODEST efforts against trafficking in persons, such as implementing public and media campaigns for anti-trafficking awareness; training government and military officials (including peace keepers); facilitating information exchange among relevant authorities; monitoring borders, train stations, airports, etc.; adopting national action plans for combating trafficking in persons; promoting cooperation with NGOs and international organizations in the country; and facilitating bilateral and/or multilateral cooperation with other governments.

Score 2:

The country demonstrates LIMITED efforts against trafficking in persons, such as implementing public and media campaigns for anti-trafficking awareness; training government and military officials (including peace keepers); facilitating information exchange among relevant authorities; monitoring borders, train stations, airports, etc.; adopting national action plans for combating trafficking in persons; promoting cooperation with NGOs and international organizations in the country; and facilitating bilateral and/or multilateral cooperation with other governments.

Score 1:

The country demonstrates NO efforts against trafficking in persons.

Appendix B. Data Description and Sources

Variable	Description	Source
Prosecution	Prosecution policy measure. Scale 5 (full compliance) to 1 (no compliance).	own calculations
Protection	Protection policy measure. Scale 5 (full compliance) to 1 (no compliance).	own calculations
Prevention	Prevention policy measure. Scale 5 (full compliance) to 1 (no compliance).	own calculations
Aggregate 3Ps	Sum of prevention, protection and prosecution scores. Scale 15 to 3.	own calculations
Tier-ranking	Compliance with US anti-trafficking law. Scale 1 (full compliance) to 3 (no compliance).	United States Department of State (2001-2010)
Control of Corruption	Around -1.63 to 2.58, with higher values corresponding to better outcomes	Kaufmann, Kraay and Mastruzzi (2009)
Democracy	Measure of democracy. +10 (full democracy) to -10 (full autocracy).	Polity IV data (Marshall and Jaggers, 2009)
Women Legislators	Share of female legislators in parliament.	World Bank Gender Statistics http://data.worldbank.org/indicator/
Women's Economic and Social Rights	Score 3 (nearly fully guaranteed) to score 0 (no rights).	Cingranelli-Richards Human Rights Dataset (2008)
Workers' Rights	Score 2 (fully granted) to 0 (severely restricted).	Cingranelli-Richards Human Rights Dataset (2008)
Intl. regime membership	Code 1 if the country is a member of the Anti-trafficking Protocol in a given year. Otherwise, 0.	http://www.unodc.org/
US aid	Share of bilateral aid from the US (% of GDP).	OECD Aid Statistics
(log) GDP pc	Per capita income in 2000 constant prices.	ERS International Macroeconomic Data Set
UNGA Voting	Bilateral similarities in voting behaviors on key votes in the UN General Assembly.	Voeten and Merdzanovic (2008), Kilby (2009)
Bilateral Trade Flows	Amounts of bilateral trade flows between two countries.	UN Commodity trade statistics database (COMTRADE, 2010)
Contiguity dummy	Code 1 if two countries share a land border or are separated by less than 150 miles of sea distance; otherwise, 0.	www.eugenesoftware.org/ (Bennett and Stam 2010)
Common Civilization dummy	Code 1 if two countries share a common civilization (Western, Islamic, Africa, Latin American, Sinic or Hindu); otherwise 0.	Russett, Oneal, and Cox (2000)
Traffic-linkage	Severity of bilateral human trafficking flows in destination country from origin or transit countries: From 9 (high flows) to 0 (no flows).	UNODC (2006)
Rule of Law	Around -2.5 to 2.5, with higher values corresponding to better outcomes.	Kaufmann, Kraay and Mastruzzi (2009)
Law and Order	Assessment on legal system and observance of law. Score 2 to 6, with higher values corresponding to better outcomes.	International Country Risk Guide. PRS Group (2009)
KOF Globalization Index	Economic, social and political globalization. Score 1-100, with a higher value corresponding to higher globalization.	Dreher et al. (2008) http://globalization.kof.ethz.ch/
